

Chapter 3: Amazon Web Services (AWS) IoT Core

After completing this chapter, you will understand the AWS IoT Core services, MQTT, and how to create Things, Policies, and Certificates.

Table of Contents

3.1	Introduction	2
3.2	MQTT	2
3.3	Amazon Web Services	3
3.4	AWS IoT Introduction	4
3.5	AWS IoT Resources	5
3.5.1	Thing	5
3.5.2	Certificate	5
3.5.3	Policy	6
3.6	Shadows	6
3.7	Topics	8
3.8	Device Shadow MQTT Topics	8
3.9	Creating Things	9
3.9.1	To create a policy:	9
3.9.2	To create a thing:	12
3.10	Transform Keys Into “C”	16
3.10.1	Amazon FreeRTOS Utility	17
3.10.2	PEMfileToCString.html Tool	18
3.10.3	Python Script format_certificates.py	20
3.11	Test Client	21
3.11.1	Subscribing to a Topic from the Test Client	21
3.11.2	Publishing to a Topic from the Test Client	22

Document conventions

Convention	Usage	Example
<i>Courier New</i>	Displays code	CY_ISR_PROTO(MyISR) ;
<i>Italics</i>	Displays file names and paths	sourcefile.hex
[bracketed, bold]	Displays keyboard commands in procedures	[Enter] or [Ctrl] [C]
Menu > Selection	Represents menu paths	File > New Project > Clone
Bold	Displays commands, menu paths and selections, and icon names in procedures	Click the Debugger icon, and then click Next .

3.1 Introduction

Whether you use AnyCloud, Amazon FreeRTOS, Mbed, or your own solution, at the heart of it your device will connect and communicate using the AWS IoT Core using MQTT. This chapter will discuss some of the concepts that are important to know when connecting your IoT device to AWS.

3.2 MQTT

MQTT is a lightweight messaging protocol that allows a device to **Publish Messages** to a specific **Topic** on a **Message Broker**. The Message Broker will then relay the message to all devices that are **Subscribed** to that **Topic**.

The format of the messages being sent in MQTT is unspecified. The message broker does not know (or care) anything about the format of the data and it is up to the system designer to specify an overall format of the data. All that being said, [JavaScript Object Notation \(JSON\)](#) has become the lingua franca of IoT.

A Topic is simply the name of a message queue e.g. `mydevice/status` or `mydevice/pressure`. The name of a topic can be almost anything you want but by convention is hierarchical and separated with forward slashes.

Publishing is the process by which a client sends a message as a blob of data to a specific topic on the message broker.

A Subscription is the request by a device to have all messages published to a specific topic sent to the client.

A Message Broker is just a server that handles the tasks:

- Establishing connections (MQTT Connect)
- Tearing down connections (MQTT Disconnect)
- Accepting subscriptions to a Topic from clients (MQTT Subscribe)
- Turning off subscriptions (MQTT Unsubscribe)
- Accepting messages from clients and pushing them to the subscribers (MQTT Publish)

MQTT provides three levels of Quality of Service (QOS):

- Level 0: At most once (each message is delivered once or never)
- Level 1: At least once (each message is certain to be delivered, possibly multiple times)
- Level 2: Exactly once (each message is certain to arrive and do so only once)

MQTT operates on TCP Ports 1883 for non-secure and 8883 for secure (TLS).

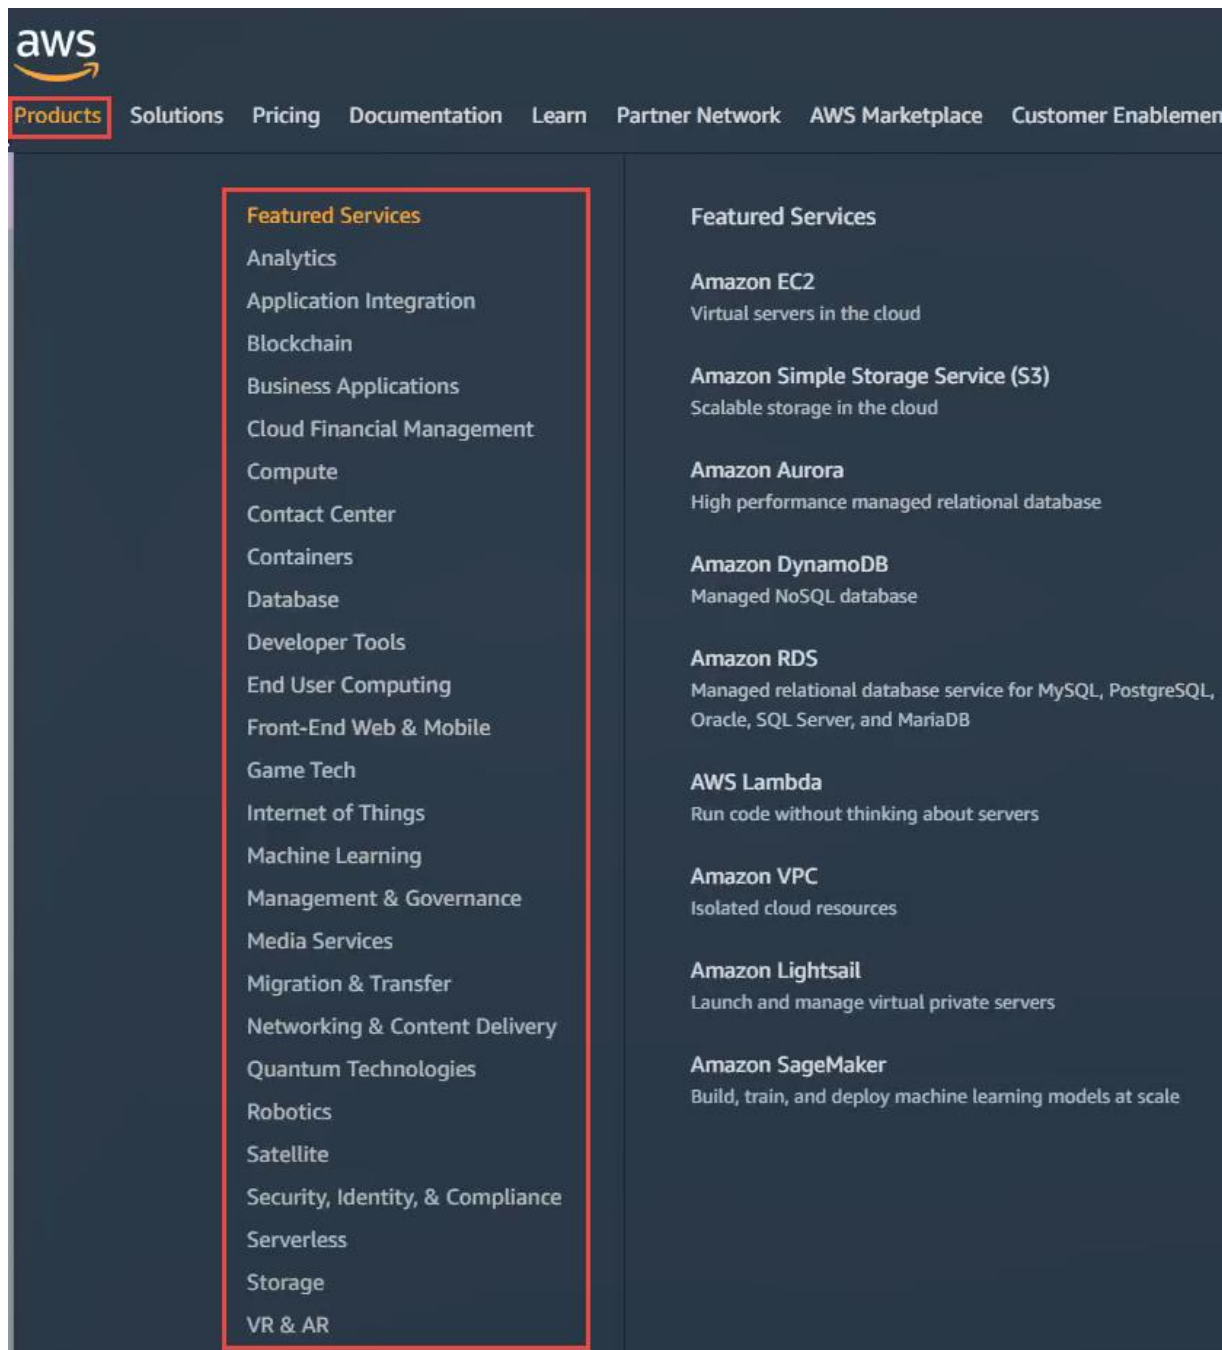

Cloud providers that support MQTT include Amazon AWS and IBM Bluemix.

3.3 Amazon Web Services

From <https://aws.amazon.com/what-is-aws/>

AWS is a secure cloud services platform, offering compute power, database storage, content delivery and other functionality (which makes more money for Amazon than their retail operations). AWS is built from a vast array of both virtual and actual servers and networks as well as a boatload of webserver software and administrative tools including the following.

You can find the complete list by going to <https://aws.amazon.com> and clicking on "Products" at the top left. There are a whole bunch of categories along the left, each of which has multiple products associated with it.

A partial list of some tools and services you may find useful:

- [AWS IoT Core](#): A cloud platform that provides Cloud services for IoT devices (the subject of this chapter).
- [Amazon Elastic Compute Cloud](#) (Amazon EC2): A virtualized compute capability, basically Linux, Windows etc. servers that you can rent.
- [AWS Lambda](#): A Cloud service that enables you to send event driven tasks to be executed.
- Storage: Large fast file systems called [Amazon Simple Storage Service \(S3\)](#) & [Amazon Elastic File System](#).
- Databases: Large fast databases called [Amazon DynamoDB](#), [Amazon Relational Database Service \(RDS\)](#), [Amazon Aurora](#).
- [Amazon Simple Notification Service](#): A platform to send messages including SMS and Email.
- [Amazon Simple Queue Service](#): A platform to send messages between servers (NOT the same thing as MQTT messages).
- [Amazon Kinesis](#): A platform to stream and analyze "massive" amounts of data. This is the plumbing for AWS IoT.
- [Amazon Virtual Private Cloud](#): A way to provision a logically isolated section of the AWS cloud where you can launch AWS resources in a virtual network that you define.
- [Amazon SageMaker](#): Machine learning for every developer and data scientist.
- Networking: Fast, fault tolerant, load balanced networks with entry points all over the world.
- Developer tools: A unified programming API supporting the AWS platform supporting a bunch of different languages.

3.4 AWS IoT Introduction

The AWS IoT Cloud service supports MQTT Message Brokers, HTTP access, **plus** a bunch of server-side functionality that provides:

- Message Broker: A virtual MQTT Message Broker.
- A virtual HTTP Server.
- Thing Registry: A web interface to manage the access to your *things*.
- Security and identity: A web interface to manage the certificates and rules about *things*. You can create encryption keys and manage access privileges.
- A "Shadow": An online cache of the most recent state of your *thing*.
- Rules Engine: An application that runs in the cloud that can subscribe to Topics and take programmatic actions based on messages – for example, you could configure it to subscribe to an "Alert" topic, and if a *thing* publishes a warning message to the alert topic, it uses Amazon SNS to send a SMS Text Message to your cell phone
- IoT Applications: A solution to build Web pages and cell phone Apps.

3.5 AWS IoT Resources

There are three types of resources in AWS: *Things*, *Certificates*, and *Policies*. The second exercise will take you step by step through the process to create each of them.

3.5.1 Thing

A *thing* is a representation of a device or logical entity. It can be a physical device or sensor (for example, a light bulb or a switch on a wall). It can also be a logical entity like an instance of an application or a physical entity that does not connect to AWS IoT but can be related to other devices that do (for example, a car that has engine sensors or a control panel).

3.5.2 Certificate

AWS IoT provides mutual authentication and encryption at all points of connection so that data is never exchanged between *things* and AWS IoT without a proven identity. AWS IoT supports X.509 certificate-based authentication. Connections to AWS use certificate-based authentication. You should attach policies to a certificate to allow or deny access to AWS IoT resources. A root CA (certification authority) certificate is used by your device to ensure it is communicating with the actual Amazon Web Services site. You can only connect your *thing* to the AWS IoT Cloud via TLS.

3.5.3 Policy

When you create your internet-connected *thing*, you must create and attach an AWS IoT policy that will determine what AWS IoT operations the *thing* may perform. AWS IoT policies are JSON documents and they follow the same conventions as AWS Identity and Access Management policies.

You can specify permissions for specific resources such as topics and shadows. Here is an example of a Policy created for a new *thing* that allows any IoT action for any resource.

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Action": [ "iot:*" ],
      "Resource": [ "*" ],
      "Effect": "Allow"
    }
  ]
}
```

3.6 Shadows

<https://docs.aws.amazon.com/iot/latest/developerguide/iot-device-shadows.html>

A *thing* shadow or device shadow is a JSON document that is used to store and retrieve current state information for a *thing* (device, app, and so on). The shadow service maintains a shadow for *thing* you connect to AWS IoT. You can use shadows to get and set the state of a *thing* over MQTT or HTTP, regardless of whether the *thing* is currently connected to the Internet. Each shadow is uniquely identified by its name.

The JSON Shadow document representing the device has the following properties:

- state:
 - desired: The desired state of the *thing*. Applications can write to this portion of the document to update the state of a *thing* without having to directly connect to a *thing*.
 - reported: The reported state of the *thing*. *Things* write to this portion of the document to report their new state. Applications read this portion of the document to determine the state of a *thing*.
- metadata: Information about the data stored in the state section of the document. This includes timestamps, in Epoch time, for each attribute in the state section, which enables you to determine when they were updated.
- timestamp: Indicates when the message was transmitted by AWS IoT. By using the timestamp in the message and the timestamps for individual attributes in the desired or reported section, a *thing* can determine how old an updated item is, even if it doesn't feature an internal clock.
- version: The document version. Every time the document is updated, this version number is incremented. Used to ensure the version of the document being updated is the most recent.

An example of a shadow document looks like this:

```
{
  "state" : {
    "desired" : {
      "color" : "RED"
      "sequence" : { "RED", "GREEN", "BLUE" }
    },
    "reported" : {
      "color" : "GREEN"
    }
  },
  "metadata" : {
    "desired" : {
      "color" : {
        "timestamp" : 12345
      },
      "sequence" : {
        "timestamp" : 12345
      }
    },
    "reported" : {
      "color" : {
        "timestamp" : 12345
      }
    }
  },
  "version" : 10,
  "timestamp" : 123456789
}
```

If you want to update the Shadow, you can publish a JSON document with just the information you want to change to the correct topic. For example, you could do:

```
{
  "state" : {
    "reported" : {
      "color": "BLUE"
    }
  }
}
```

Note that spaces and carriage returns are optional, so the above could be written as:

```
{"state":{"reported":{"color": "BLUE"}}}
```

3.7 Topics

You can interact with AWS using either MQTT or HTTP. While topics are an MQTT concept, you will see later that topic names are important even when using HTTP to interact with shadows. The AWS Message Broker will allow you to create Topics with almost any name, with one exception: Topics named `$aws/...` are reserved by AWS IoT for specific functions.

As the system designer, you are responsible for defining what the topics mean and do in your system. Some [best practices](#) include:

1. Don't use a leading forward slash.
2. Don't use spaces.
3. Keep the topic short and concise.
4. Use only ASCII characters.
5. Embed a unique identifier e.g. the name of the *thing*.

For example, a good topic name for a temperature sensing device might be: `myDevice/temperature`.

3.8 Device Shadow MQTT Topics

<https://docs.aws.amazon.com/iot/latest/developerguide/device-shadow-mqtt.html>

Each *thing* that you have will have a group of topics of the form

`$aws/things/<thingName>/shadow/<type>` which allow you to publish and subscribe to topics relating to the shadow. The specific shadow topics that exist are:

MQTT Topic Suffix <type>	Function
<code>/update</code>	The JSON message that you publish to this topic will become the new state of the shadow.
<code>/update/accepted</code>	AWS will publish a message to this topic in response to a message to <code>/update</code> indicating a successful update of the shadow.
<code>/update/documents</code>	When a document is updated via a publish to <code>/update</code> , the entire updated document is published to this topic.
<code>/update/rejected</code>	AWS will publish a message to this topic in response to a message to <code>/update</code> indicating a rejected update of the shadow.
<code>/update/delta</code>	After a message is sent to <code>/update</code> , the AWS will send a JSON message if the desired state and the reported state are not equal. The message contains all attributes that don't match.
<code>/get</code>	If a <i>thing</i> publishes a message to this topic, AWS will respond with a message to either <code>/get/accepted</code> or <code>/get/rejected</code> with the current state of the shadow.
<code>/get/accepted</code>	
<code>/get/rejected</code>	
<code>/delete</code>	If a <i>thing</i> publishes a message to this topic, AWS will delete the shadow document.
<code>/delete/accepted</code>	AWS will publish to this topic when a successful <code>/delete</code> occurs.
<code>/delete/reject</code>	AWS will publish to this topic when a rejected <code>/delete</code> occurs.

The update topic is useful when you want to update the state of a *thing* on the cloud. For example, if you have a *thing* called `myThing` and want to update a value called `temperature` to 25 degrees in the state of the *thing*, you would publish (for MQTT) or POST (for HTTP) using the following topic and message:

topic: `$aws/things/myThing/shadow/update`

message: `{"state":{"reported":{"temperature":25}}}`

Once the message is received, the MQTT message broker will publish to the `/accepted` and `/documents` topics with the appropriate information.

If you are using the MQTT test server to subscribe to topics, you can use the `#` character as a wildcard at the end of a topic to subscribe to multiple topics. For example, you can use `$aws/things/theThing/shadow/#` to subscribe to all shadow topics for the *thing* called `theThing`.

You can also use the plus sign (+) as a wildcard in the middle of a topic to subscribe to multiple topics. For example, you can use `$aws/things/+/shadow/update` to subscribe to update topics for all shadows.

3.9 Creating Things

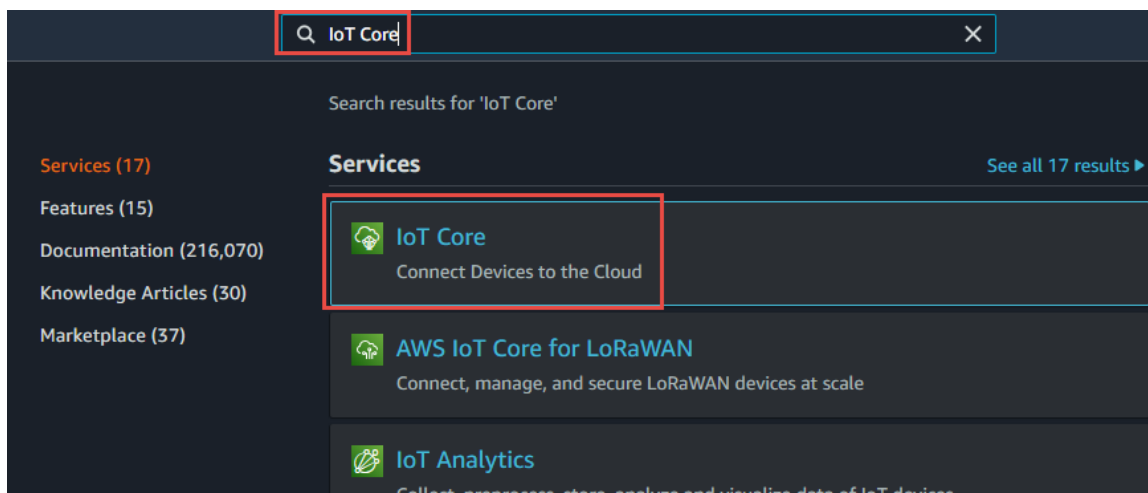

Now let's step through the process of manually creating a new *thing* in AWS. Note that these steps may be slightly different when you try it because Amazon updates their web interface often, but it should be close enough to understand.

At the end of the *thing* creation process, AWS will ask you which policy to attach to your *thing*. You can have a generic policy that applies to multiple *things*, or you can have a specific policy that applies to each *thing*. This is a security architecture decision that the applications developer is responsible for. In this case we will create a generic policy first and then we will create the *thing* after that.

3.9.1 To create a policy:

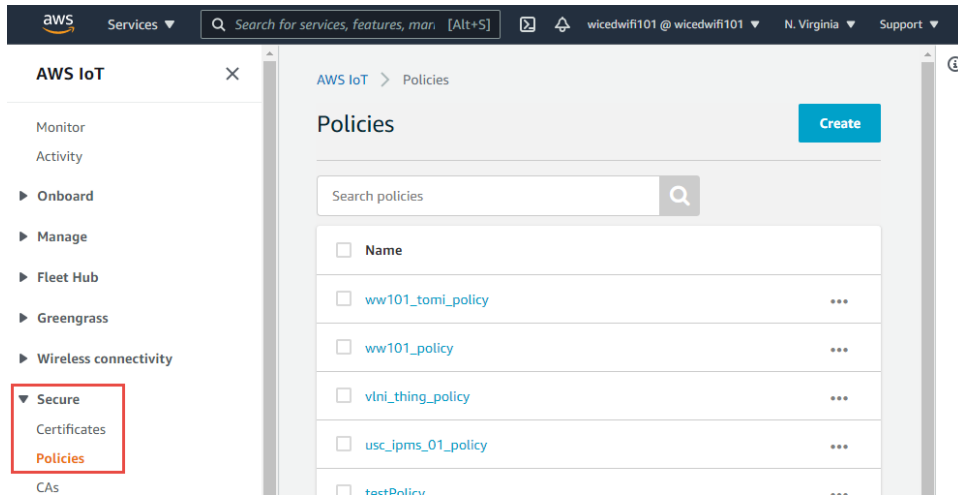

1. Go to <https://aws.amazon.com/console/> and login using the credentials provided. If you are doing this class on your own, you will need to create an account.
2. If needed, click the “AWS” icon in the top left.
3. In the search box at the top, enter **IoT Core** and select it from the search results.

4. On the left, click on **Secure > Policies**.

You will be able to look at (and search) all the policies attached to your account.

5. To create a new policy, click **Create**. On the “Create a Policy” page:

Create a policy

Create a policy to define a set of authorized actions. You can authorize actions on one or more resources (things, topics, topic filters). To learn more about IoT policies go to the [AWS IoT Policies documentation page](#).

Name

Add statements

Policy statements define the types of actions that can be performed by a resource. **Advanced mode**

Action

Resource ARN

Effect

☒ Allow ☐ Deny

Remove

Add statement

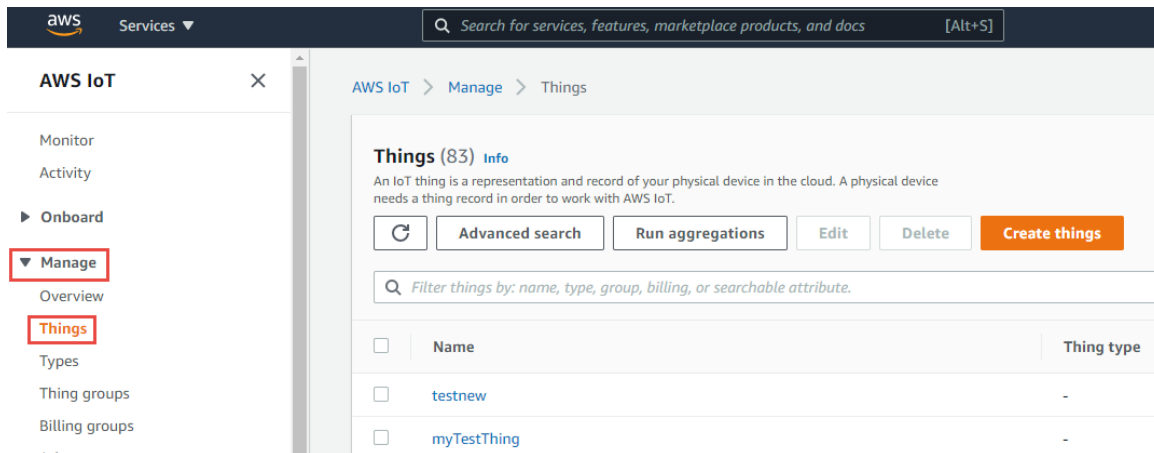

Create

- Give the policy a **Name** (in this case `mypolicy`). Your name should reflect your security architectural objectives.
- Then assign the specific **Action**. In this case I am using `iot:*` which means this policy will allow all IoT actions (i.e. connect, publish).
- Specify which **Resource** that this policy applies to. To simplify this, I use “*” meaning all resources. However, there are a complicated set of rules that let you constrain the resource based on certificates, connection types etc.
- You can read about those rules here:
- <https://docs.aws.amazon.com/iot/latest/developerguide/iot-policies.html>
- Check the box under Effect for "Allow" so that your specified actions are allowed on the specified resources. Note that you can also create policies that deny actions on specified resources to limit things.
- Click **Create** at the bottom to make the policy.

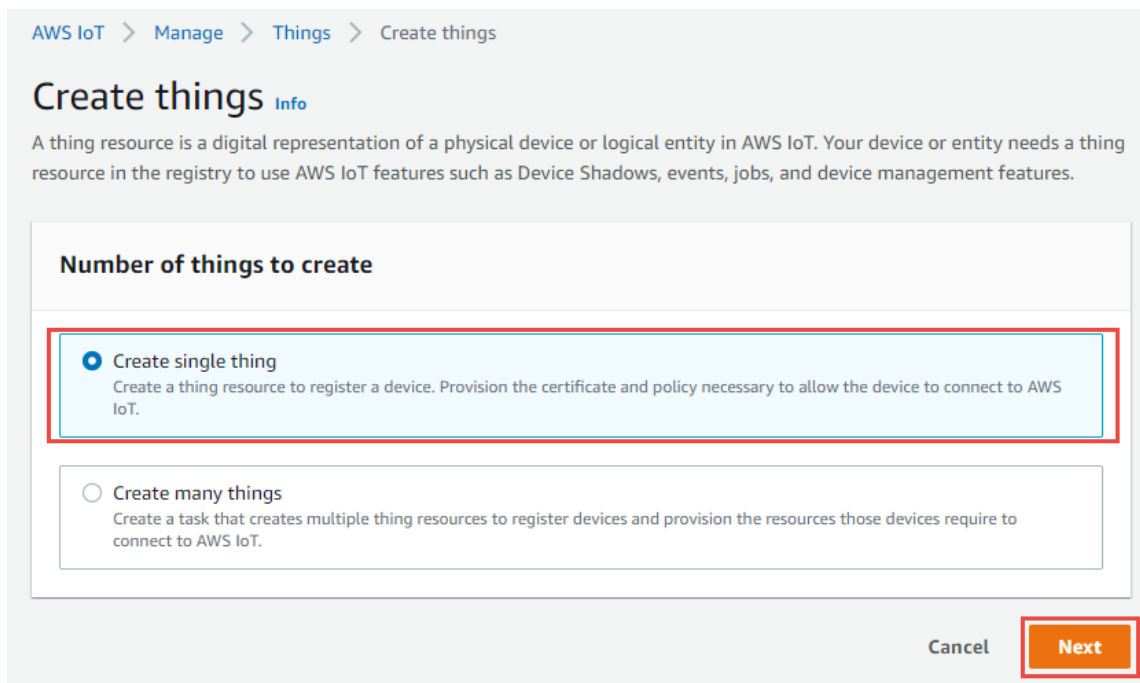

3.9.2 To create a thing:

1. On the left side, select **Manage > Things**.

2. Once there, click **Create things** to make a new *thing*.
3. On the “Creating AWS IoT things” page, choose **Create single thing** and click **Next**.

4. Give it a unique name. Under **Device Shadow**, select **Unnamed shadow (classic)**. When done, click **Next**.

Specify thing properties [Info](#)

A thing resource is a digital representation of a physical device or logical entity in AWS IoT. Your device or entity needs a thing resource in the registry to use AWS IoT features such as Device Shadows, events, jobs, and device management features.

Thing properties [Info](#)

Thing name

myTestThing

Enter a unique name containing only: letters, numbers, hyphens, colons, or underscores. A thing name can't contain any spaces.

Additional configurations

You can use these configurations to add detail that can help you to organize, manage, and search your things.

- ▶ Thing type - *optional*
- ▶ Searchable thing attributes - *optional*
- ▶ Thing groups - *optional*
- ▶ Billing group - *optional*

Device Shadow [Info](#)

Device Shadows allow connected devices to sync states with AWS. You can also get, update, or delete the state information of this thing's shadow using either HTTPs or MQTT topics.

☐ No shadow

☐ Named shadow
Create multiple shadows with different names to manage access to properties, and logically group your devices properties.

☒ Unnamed shadow (classic)
A thing can have only one unnamed shadow.

▶ Edit shadow statement - *optional*

Cancel

Next

The security associated with a *thing* is controlled using X.509 certificates. Each *thing* should have a certificate attached to it. The easiest (and probably best) thing to do is let AWS auto-generate a certificate for you.

5. Make sure **Auto-generate a new certificate** is selected and click **Next**.

Configure device certificate - optional [Info](#)

A device requires a certificate to connect to AWS IoT. You can choose how you to register a certificate for your device now, or you can create and register a certificate for your device later. Your device won't be able to connect to AWS IoT until it has an active certificate with an appropriate policy.

Device certificate

☒ **Auto-generate a new certificate (recommended)**
Generate a certificate, public key, and private key using AWS IoT's certificate authority.

☐ **Use my certificate**
Use a certificate signed by your own certificate authority.

☐ **Upload CSR**
Register your CA and use your own certificates on one or many devices.

☐ **Skip creating a certificate at this time**
You can create a certificate for this thing and attach a policy to the certificate at a later time.

Cancel Previous Next

6. The next page asks if you want to attach a policy to the certificate. Select the policy that you created earlier from the list. You can enter all or part of the policy name in the search box to filter the list.

Attach policies to certificate - optional [Info](#)

AWS IoT policies grant or deny access to AWS IoT resources. Attaching policies to the device certificate applies this access to the device.

Policies (1/32) Refresh Create policy

Select up to 10 policies to attach to this certificate.

X 3 matches < 1 > Settings

<input type="checkbox"/>	Name
<input checked="" type="checkbox"/>	mypolicy
<input type="checkbox"/>	myiotpolicy
<input type="checkbox"/>	myiksh11

Cancel Previous Create thing

7. Once you have selected the policy that you want, click on **Create Thing**. This will create the *Thing* along with an AWS signed certificate, a public key and a private key.

You will see page with a list of the certificates and keys. You **MUST** download the certificate and key files from this screen as it will be the last time you have the opportunity. **Do this now!**

Download certificates and keys

Download certificate and key files to install on your device so that it can connect to AWS.

Device certificate

You can activate the certificate now, or later. The certificate must be active for a device to connect to AWS IoT.

Device certificate
956da356dd2...te.pem.crt

Deactivate certificate

 Download

Key files

The key files are unique to this certificate and can't be downloaded after you leave this page. Download them now and save them in a secure place.

 This is the only time you can download the key files for this certificate.

Public key file
956da356dd203ea607c819a...eb83f52-public.pem.key

 Download

Private key file
956da356dd203ea607c819a...b83f52-private.pem.key

 Download

Root CA certificates

Download the root CA certificate file that corresponds to the type of data endpoint and cipher suite you're using. You can also download the root CA certificates later.

Amazon trust services endpoint
RSA 2048 bit key: Amazon Root CA 1

 Download

Amazon trust services endpoint
ECC 256 bit key: Amazon Root CA 3

 Download

If you don't see the root CA certificate that you need here, AWS IoT supports additional root CA certificates. These root CA certificates and others are available in our developer guides. [Learn more](#) 

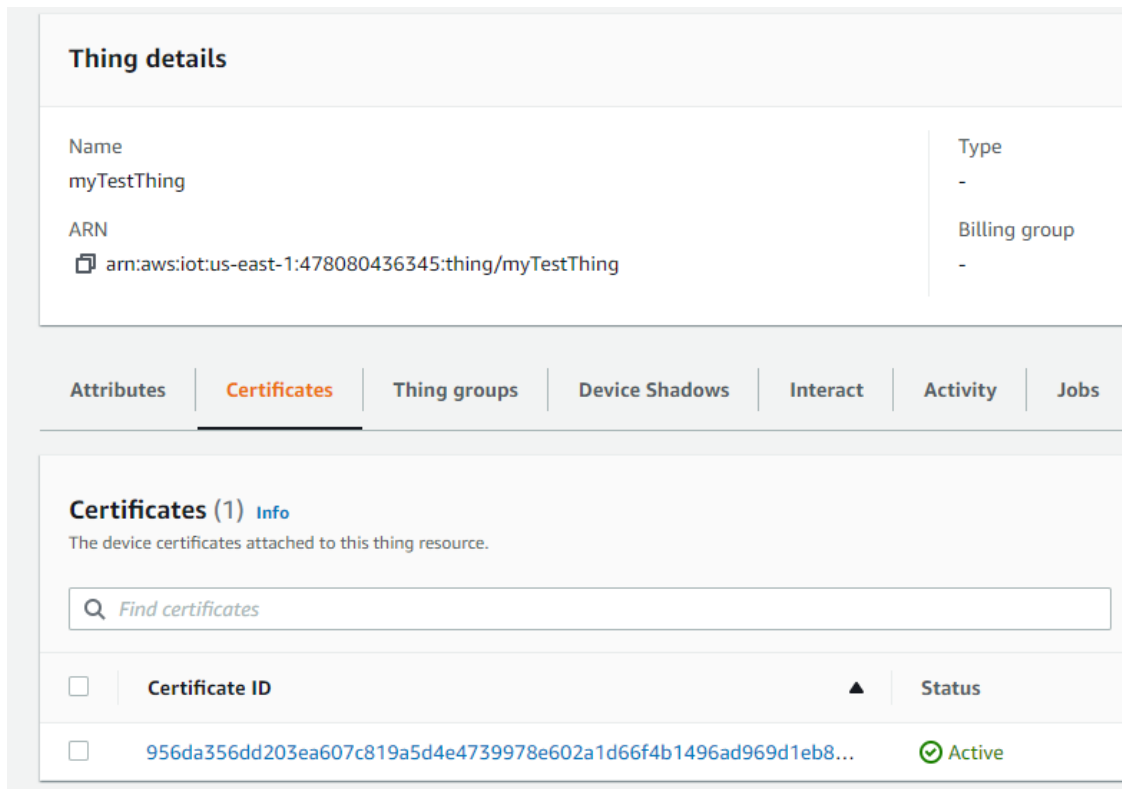

Done

Note: You should download the first three files for every new certificate that you create.

Note: When making a TLS connection, it is best for your device to verify the certificate of the other side. This verifies that it is really Amazon on the other side - not some nefarious site pretending to be Amazon. To do this, you will need to include the AWS root certificate in your firmware. You only need to download that certificate one time since it is Amazon's certificate. You can use the same certificate in all of your projects that connect to AWS

8. Once you have all of the files downloaded, click **Done** to close the window.
9. Click on the name of your *Thing* to see information about it. If you click on the Certificate ID from the Certificates tab, you will see information about the certificate including the policy that is attached to it. To get IoT to work, you need a thing that has an active certificate with a policy attached to it that allows IoT actions.

The screenshot shows the 'Thing details' page in the AWS IoT console. The 'Name' is 'myTestThing' and the 'ARN' is 'arn:aws:iot:us-east-1:478080436345:thing/myTestThing'. The 'Type' is '-' and the 'Billing group' is '-'. Below this is a tabbed interface with 'Certificates' selected. The 'Certificates (1)' section shows a search bar and a table with one certificate. The certificate ID is '956da356dd203ea607c819a5d4e4739978e602a1d66f4b1496ad969d1eb8...' and its status is 'Active'.

Thing details	
Name myTestThing	Type -
ARN  arn:aws:iot:us-east-1:478080436345:thing/myTestThing	Billing group -

Attributes	Certificates	Thing groups	Device Shadows	Interact	Activity	Jobs
Certificates (1) Info The device certificates attached to this thing resource.						
<input type="text" value="Find certificates"/>						
<input type="checkbox"/>	Certificate ID	▲	Status			
<input type="checkbox"/>	956da356dd203ea607c819a5d4e4739978e602a1d66f4b1496ad969d1eb8...		 Active			

3.10 Transform Keys Into “C”

Once you have your certificates and keys you need to turn them into a format that is usable by your firmware. If you are using Amazon FreeRTOS, the easiest way to change your certificate into a C-File is to use the utility provided by Amazon FreeRTOS. See section [3.10.1](#).

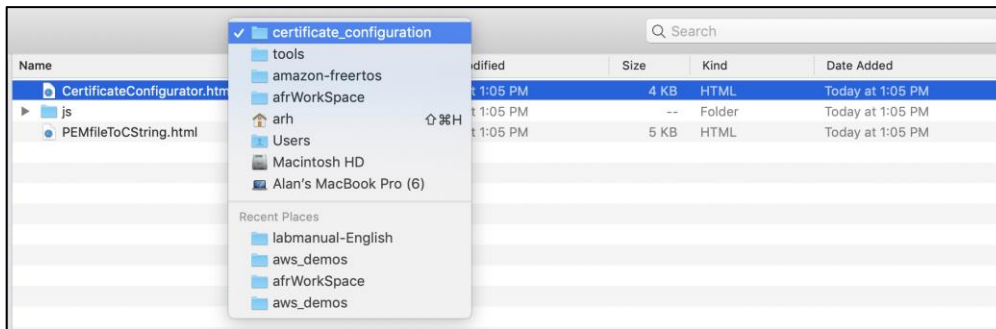

If you are using AWS without Amazon FreeRTOS or Mbed, you will need to do one of the following:

- convert the certificate and keys to C strings on your own;
- use the PEMfileToCString.html utility (if you have the Amazon FreeRTOS repository cloned);
- use a Python script that we will provide.

The latter two methods are described in sections [3.10.2](#) and [3.10.3](#). For Mbed, the file `aws_config.h` contains examples of what the strings look like. For AnyCloud, examples will be provided in the file containing the keys - the specific file varies by code example.

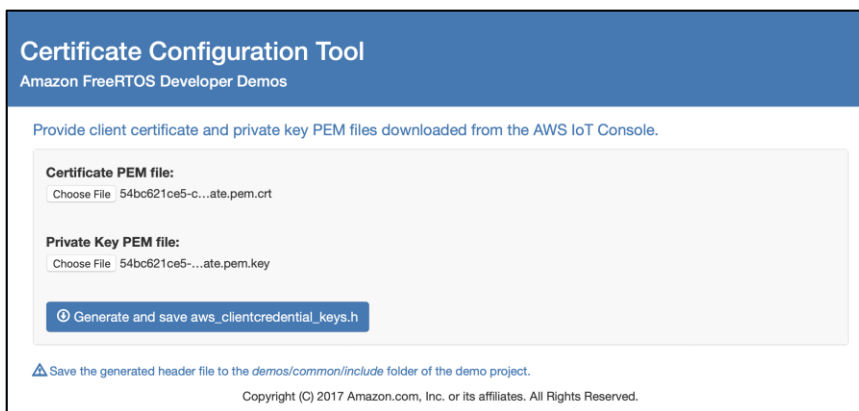

3.10.1 Amazon FreeRTOS Utility

1. First, go to the `amazon-freertos/tools/certificate_configuration` directory and open the `CertificateConfigurator.html` in a web browser.

Note: If you have not downloaded the amazon-freertos repository yet, you can download it using:
`git clone https://github.com/infineon/amazon-freertos.git`

2. Select your Certificate and Private Key files. Then click **Generate and save...**

This will make a C-header file named `aws_clientcredential_keys.h` and download it to your PC. Move the file to the `amazon-freertos/demos/include` directory if your browser does not put it there by default. This is just a normal C-header file with `#defines` for the `keyCLIENT_CERTIFICATE_PEM`, `keyCLIENT_PRIVATE_KEY_PEM`. And this file is named exactly the right thing for the Amazon FreeRTOS demo.

The file will look like this:

```
#ifndef AWS_CLIENT_CREDENTIAL_KEYS_H
#define AWS_CLIENT_CREDENTIAL_KEYS_H

#include <stdint.h>

/*
 * PEM-encoded client certificate.
 * Must include the PEM header and footer:
 * "-----BEGIN CERTIFICATE-----\n"
 * "...base64 data...\n"
 * "-----END CERTIFICATE-----"
 */
#define keyCLIENT_CERTIFICATE_PEM \
"-----BEGIN CERTIFICATE-----\n" \
"MIIDWjCCAqKgAwIBAgIWAOKY9SFEqyUMZK13nNVHcP9lncTKMA0GCSqGSIb3DQEBAQ\n" \

"-----END CERTIFICATE-----"
```

3.10.2 PEMfileToCString.html Tool

You can also use the Amazon FreeRTOS Tool called *PEMfileToCString.html* to convert any (single) PEM file into a C-String. This is useful for applications that use AWS without Amazon FreeRTOS or for Mbed applications. However, you must have the Amazon FreeRTOS repo to use this tool.

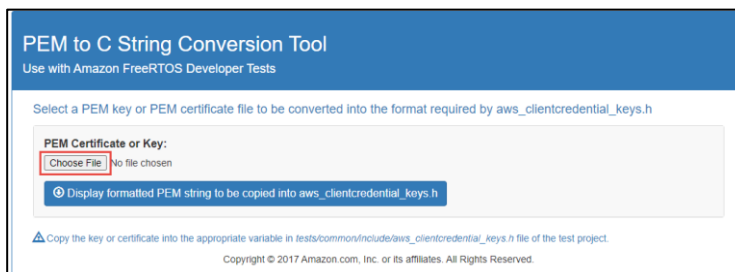

1. Go to the *amazon-freertos/tools/certificate_configuration* directory and open the *PEMfileToCString.html* file in a web browser.

Note: If you have not downloaded the *amazon-freertos* repository yet, you can download it using:

```
git clone https://github.com/infineon/amazon-freertos.git
```

2. For example, to convert the Root Certificate for Amazon, click **Choose File**.

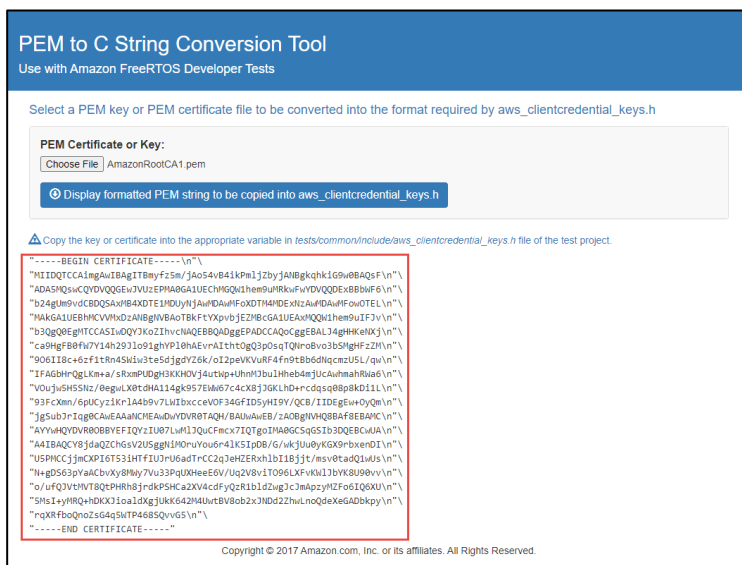

3. Select the *AmazonRootCA1.pem* file and click **Choose** or **Open**.

4. Then click **Display formatted PEM string...** to show the formatted string.

5. This string can then be copy/pasted into your keys file (or any other C-file).

For instance, you could add the string to the file *aws_clientcredential_keys.h* for Amazon FreeRTOS or to *aws_config.h* for Mbed. Make sure you copy each key string into the correct #define or array in your application.

3.10.3 Python Script `format_certificates.py`

The final option to convert the certificates to strings is to use the Python script `format_certificates.py`. This script is available in the class material under the *Scripts* directory. To use it:

1. Put the script and your certificates in a directory as shown below.

The private key file name must end with `private.pem.key`, the certificate file name must end with `certificate.pem.crt` and the Amazon Root CA must end with `CA1.pem`.

2. Open an terminal and enter:

```
python ./format_certificates.py
```

This prints the formatted strings to the terminal. You can copy/paste these to your application code. Make sure you copy each key string into the correct `#define` or array in your application.

Note: The script doesn't do anything with the public key because it is not used by your firmware. Rather, it is needed by whatever will connect with your kit - in this case Amazon.

3.11 Test Client

The AWS website has an MQTT Test Client that you can use to test publishing and subscribing to topics. Think of it as a terminal window into your message broker, or as a generic IoT *thing* that can publish and subscribe.

3.11.1 Subscribing to a Topic from the Test Client

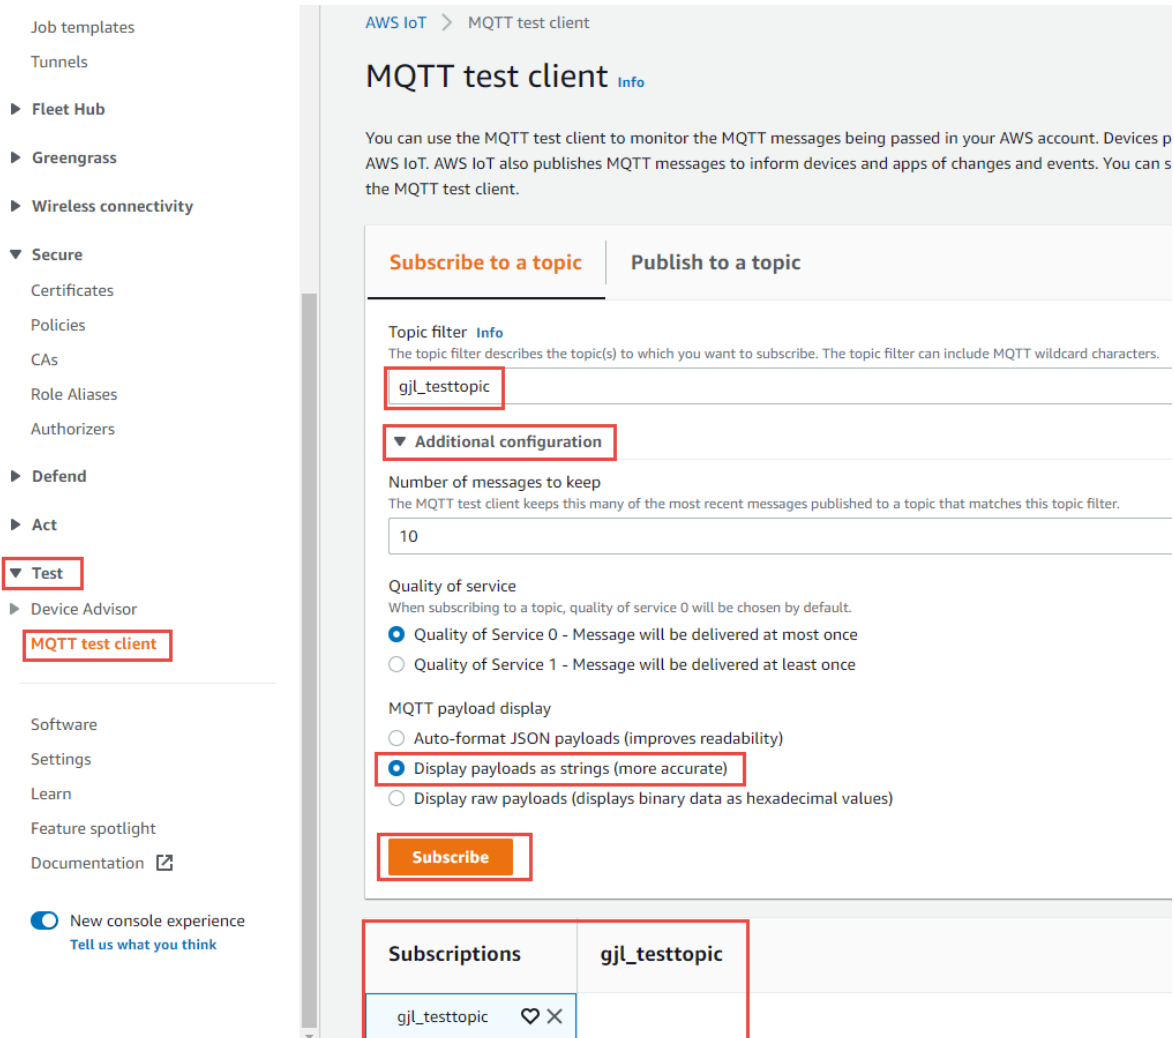

1. Select **Test > MQTT test client** from the panel on the left of the screen.
2. Enter a topic that you want to subscribe to such as **<your_initials>_testtopic** in the **Topic filter** box.

Put your initials or some other unique string in the topic if you are using the class AWS account. If not, you may see messages from someone else publishing to the same topic.

3. Under **Additional configuration**, select **Display payloads as strings**, and click on **Subscribe**. Messages to that topic will show up at the bottom of the window

The screenshot displays the AWS IoT MQTT test client interface. On the left, the navigation sidebar is visible, with the 'Test' section expanded and 'MQTT test client' selected. The main content area shows the 'Subscribe to a topic' tab. The 'Topic filter' field contains 'gjl_testtopic'. Under the 'Additional configuration' section, the 'Display payloads as strings (more accurate)' option is selected. The 'Subscribe' button is prominently displayed. At the bottom, a 'Subscriptions' list shows the subscribed topic 'gjl_testtopic' with a heart icon and a close button.

3.11.2 Publishing to a Topic from the Test Client

Now that I am subscribed to a topic, I can publish messages to that topic from another instance of the MQTT test client.

1. Click on the **Publish to a topic** tab and fill in the name of the topic that you subscribed to earlier. The name must be exactly the same (including case).

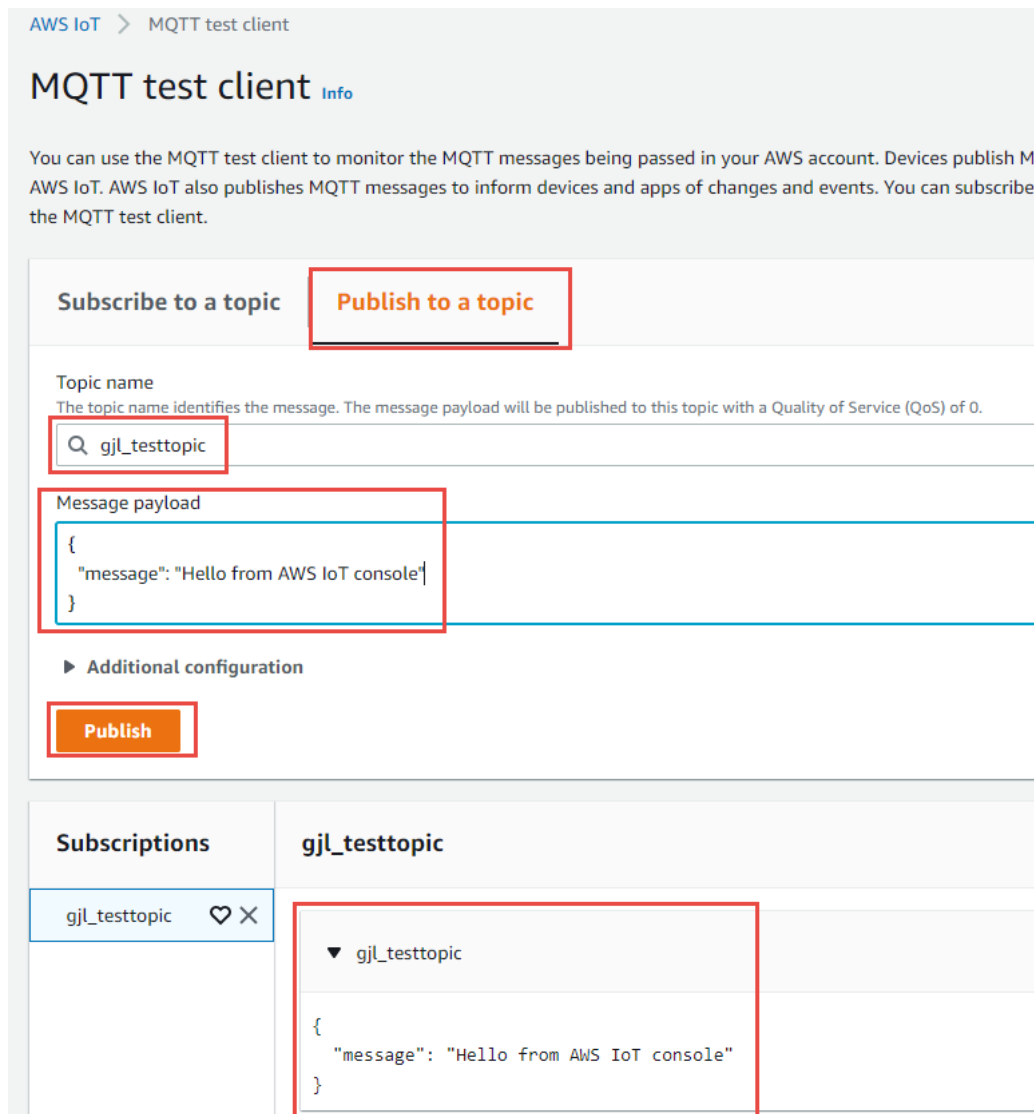

Note: If possible, team up with another student if you can so that one person subscribes and the other publishes to the same topic. This will demonstrate that the messages are going through the AWS broker.

Note: If you are doing this on your own, you can open a new browser window so that you can publish from one and subscribe from the other. You can even use 2 different computers if you wish.

2. Type in your message and click **Publish**.

The message that was sent will show up in the Subscriptions section at the bottom of the page.

AWS IoT > MQTT test client

MQTT test client [Info](#)

You can use the MQTT test client to monitor the MQTT messages being passed in your AWS account. Devices publish M AWS IoT. AWS IoT also publishes MQTT messages to inform devices and apps of changes and events. You can subscribe the MQTT test client.

Subscribe to a topic

Publish to a topic

Topic name
The topic name identifies the message. The message payload will be published to this topic with a Quality of Service (QoS) of 0.
